Contents

Chapter 1

Introduction

The book describes clang compiler frontend internals. Architecture design is described and also practical code examples provided [2].

Chapter 2

Environment setup

The chapter describes basic steps to be done to setup the environment be used for future experiments with clang.

2.1 Source code compilation

we are going to compile our source code in debug mode to be suitable for future investigations with debugger.

2.1.1 Getting the source code

The clang source is a part of LLVM. You can get it with the following command

```
git clone https://github.com/llvm/llvm-project.git
cd llvm-project
```

2.1.2 Configuration with cmake

Create a build folder where the compiler and related tools will be built

```
mkdir build
cd build
```

Run configure script

```
cmake -G Ninja -DLLVM_ENABLE_PROJECTS="clang;clang-tools-extra" \
-DLLVM_USE_LINKER=gold -DLLVM_USE_SPLIT_DWARF=ON ../llvm
```

The are several options specified:

- **LLVM_ENABLE_PROJECTS="clang;clang-tools-extra"** specifies LLVM projects that we care about
- **LLVM_USE_LINKER=gold** - uses gold linker
- **LLVM_USE_SPLIT_DWARF=ON** - spits debug information into separate files. This option saves disk space as well as memory consumption during the LLVM build. The option require compiler used for clang build to support it

2.1.3 Build

The build is trivial

```
ninja clang
```

You can also run unit and end-to-end tests for the compiler with

```
ninja check-clang
```

The compiler binary can be found as **bin/clang** at the build folder.

Chapter 3

Architecture

You can find some info about clang internal architecture and relation with other LLVM components.

When we spoke about **clang** we should separate 2 things:

- driver
- compiler frontend

Both of them are called **clang** but perform different operations. The driver invokes different stages of compilation process (see fig. 3.1). The stages are standard for ordinary compiler and nothing special is there:

- Frontend: it does lexical analysis and parsing.
- Middle-end: it does different optimization on the intermediate representation (LLVM-IR) code
- Backend: Native code generation
- Assembler: Running assembler
- Linker: Running linker

The driver is invoked by the following command

Figure 3.1: Clang driver

```
clang main.cpp -o main -lstdc++
```

The driver also adds a lot of additional arguments, for instance search paths for system includes that could be platform specific. You can use `-###` clang option to print actual command line used by the driver

```
$clang -### main.cpp -o main -lstdc++
clang version 12.0.1 (Fedora 12.0.1-1.fc34)

```

Chapter 4

Features

You can find some info about different clang features at the chapter

4.1 Precompiled headers

Precompiled headers or **pch** is a clang feature that was designed with the goal to improve clang frontend performance. The basic idea was to create AST for a header file and reuse the AST for some purposes.

4.1.1 User guide

Generate you pch file is simple [1]. Suppose you have a header file with name **header.h**:

```
#pragma once

void foo() {
}
```

then you can generate a pch for it with

```
clang -x c++-header header.h -o header.pch
```

the option **-x c++-header** was used there. The option says that the header file has to be treated as a c++ header file. The output file is **header.pch**.

The precompiled headers generation is not enough and you may want to start using them. Typical C++ source file that uses the header may look like

```
// test pchs

#include "header.h"

int main() {
  foo();
  return 0;
}
```

As you may see, the header is included as follows

```
  ...
#include "header.h"
  ...
```

By default clang will not use a pch at the case and you have to specify it explicitly with

```
clang -include-pch header.pch main.cpp -o main -lstdc++
```

We can check the command with debugger and it will give us

```
$ lldb ~/local/llvm-project/build/bin/clang -- -cc1
↪  -include-pch header.pch main.cpp -fsyntax-only
...
(lldb) b clang::ASTReader::ReadAST
...
(lldb) r
...
   4231   llvm::SaveAndRestore<SourceLocation>
-> 4232     SetCurImportLocRAII(CurrentImportLoc, ImportLoc);
   4233   llvm::SaveAndRestore<Optional<ModuleKind>>
    ↪  SetCurModuleKindRAII(
   4234       CurrentDeserializingModuleKind, Type);
   4235
(lldb) p FileName
(llvm::StringRef) $0 = (Data = "header.pch", Length = 10)
```

Note that only the first –**include-pch** option will be processed, all others will be ignored. It reflects the fact that there can be only one precompiled header for a translation unit.

4.2 Modules

TBD
