Notations

$[\mathbf{C}, \mathbf{D}]$ **Fun** category (Example 4.2)

$\alpha \circ \beta$ Vertical composition of natural transformations (circle dot)

$\alpha \star \beta$ Horizontal composition of natural transformations (star dot)

αH Left whiskering

α, β Natural transformation (Greek small letters)

$\alpha : F \rightrightarrows G$ Natural transformation (arrow with dot)

$\mathbf{C}_{\mathbf{M}}$ Kleisli category

\mathbf{C} Category (bold capital Latin letter)

\mathbf{C}^{op} Opposite category

$\text{cod } f$ Codomain

$\text{dom } f$ Domain

$\text{hom}(a, b)$ set of Morphisms between a and b

$\text{hom}_{\mathbf{C}}(a, b)$ Set of morphisms

$1_{\mathbf{C} \Rightarrow \mathbf{C}}$ Identity functor

$1_{a \rightarrow a}$ Identity morphism

$1_{F \rightrightarrows F}$ Identity natural transformation

$\langle M, \mu, \eta \rangle$ Monad

\mathcal{H}_n finite dimensional Hilbert space

$a \cong_f b$ there is an Isomorphism f between a and b

a, b **Objects** (Latin small letters)

a^b **Exponential**

$F \circ G$ **Functor composition** (circle dot)

$f \circ g$ Morphism composition (circle dot)

F, G **Functor** (capital Latin letter)

f, g, h **Morphism** (Latin small letter)

$F : \mathbf{C} \Rightarrow \mathbf{D}$ **Functor** (double arrow)

$f : a \rightarrow b$ **Morphism** (simple arrow)

$H\alpha$ **Right whiskering**

TBD To Be Defined (later)

Introduction

You just looked at yet another introduction to Category Theory. The subject mostly consists of a lot of definitions that are related each others and I wrote the book to collect all of them in one place to be easy checked and updated in future when I decide to refresh my knowledge about the field of math. Therefore the book was written mostly for my category theory studying purposes but I will appreciate if somebody else find it useful.

The topics(chapters) cover the base definitions ([Object](#), [Morphism](#) and [Category](#)), [Functor](#), [Natural transformation](#), [Monad](#) and also include important results from the category theory such as Yoneda's lemma (see chapter 6) and Curry-Howard-Lambek correspondence (see section 2.6).

There are a lot of examples in each chapter. The examples cover different category theory application areas. I assume that the reader is familiar with the corresponding area and the example(s) can be passed if not. I.e. anyone can choose the suitable example(s) for (s)he.

The most important examples are related to the set theory. The set theory and category theory are very close related. Each one can be considered as an alternative view to another one.

There are a lot of examples from programming languages which include Haskell, Scala, C++. The source files for programming languages examples (Haskell, C++, Scala) can be found on github repository [8].

The examples from physics are related to quantum mechanics that is the most known for me. For the examples I am inspired by the Bob Coecke article [1].

Chapter 1

Base definitions

1.1 Definitions

1.1.1 Object

Definition 1.1 (Class). A class is a collection of sets (or sometimes other mathematical objects) that can be unambiguously defined by a property that all its members share.

Definition 1.2 (Object). In category theory object is considered as something that does not have internal structure (aka point) but has a property that makes different objects belong to the same [Class](#)

Remark 1.3 (Class of Objects). The [Class](#) of [Objects](#) will be marked as $\text{ob}(\mathbf{C})$ (see fig. 1.1).

Figure 1.1: Class of objects $\text{ob}(\mathbf{C}) = \{a, b, c, d\}$

1.1.2 Morphism

Morphism is a kind of relation between 2 **Objects**.

Definition 1.4 (Morphism). A relation between two **Objects** a and b

$$f_{ab} : a \rightarrow b$$

is called *morphism*. Morphism assumes a direction i.e. one **Object** (a) is called *source* and another one (b) *target*.

The **Set** of all morphisms between objects a and b is denoted as $\text{hom}(a, b)$.

The important remark about morphisms is below

Remark 1.5 (Morphism). The morphism has to be considered as a relation between objects. We will avoid standard (from set theory) notation for morphisms: $f(a) = b$. The reason for this is the following. Let $f_1 : a \rightarrow b$ and $f_2 : a \rightarrow b$ are 2 different morphisms. The notation $f_1(a) = b, f_2(a) = b$ leads to incorrect conclusion that $f_1 = f_2$.

For instance if $a = b = \mathbb{R}$ then 2 functions $f_1(x) = x, f_2(x) = -x$ set 2 different ordering on \mathbb{R} and as result have not to be considered as the same functions.

Definition 1.6 (Domain). Given a **Morphism** $f : a \rightarrow b$, the **Object** a is called domain and denoted as $\text{dom } f$.

Definition 1.7 (Codomain). Given a **Morphism** $f : a \rightarrow b$, the **Object** b is called codomain and denoted as $\text{cod } f$.

Morphisms have several properties. ¹

Axiom 1.8 (Composition). If we have 3 **Objects** a, b and c and 2 **Morphisms**

$$f_{ab} : a \rightarrow b$$

and

$$f_{bc} : b \rightarrow c$$

then there exists **Morphism**

$$f_{ac} : a \rightarrow c$$

such that

$$f_{ac} = f_{bc} \circ f_{ab}$$

¹The properties don't have any proof and postulated as axioms

Remark 1.9 (Composition). The equation

$$f_{ac} = f_{bc} \circ f_{ab}$$

means that we apply f_{ab} first and then we apply f_{bc} to the result of the application i.e. if our objects are sets and $x \in a$ then

$$f_{ac}(x) = f_{bc}(f_{ab}(x)),$$

where $f_{ab}(x) \in b$.

Axiom 1.10 (Associativity). The *Morphisms Composition* (*Axiom 1.8*) should follow associativity property:

$$f_{ce} \circ (f_{bc} \circ f_{ab}) = (f_{ce} \circ f_{bc}) \circ f_{ab} = f_{ce} \circ f_{bc} \circ f_{ab}.$$

Definition 1.11 (Identity morphism). For every *Object* a we define a special *Morphism* $\mathbf{1}_{a \rightarrow a} : a \rightarrow a$ with the following properties: $\forall f_{ab} : a \rightarrow b$

$$\mathbf{1}_{a \rightarrow a} \circ f_{ab} = f_{ab} \tag{1.1}$$

and $\forall f_{ba} : b \rightarrow a$

$$f_{ba} \circ \mathbf{1}_{a \rightarrow a} = f_{ba}. \tag{1.2}$$

This morphism is called as *identity morphism*.

Note that *Identity morphism* is unique, see *Identity is unique* (*Theorem 2.3*) below.

Definition 1.12 (Commutative diagram). A commutative diagram is a diagram of *Objects* (also known as vertices) and *Morphisms* (also known as arrows or edges) such that all directed paths in the diagram with the same start and endpoint lead to the same result by composition

The following diagram commutes if $f_{ab} = f_{cb} \circ f_{ac}$.

Remark 1.13 (Class of Morphisms). The *Class of Morphisms* will be marked as $\text{hom}(\mathbf{C})$ (see fig. 1.2)

Figure 1.2: Class of morphisms $\text{hom}(\mathbf{C}) = \{f, g, h\}$, where $h = f \circ g$

Definition 1.14 (Monomorphism). If $\forall g_1, g_2$ the equation

$$f \circ g_1 = f \circ g_2$$

leads to

$$g_1 = g_2$$

then f is called *monomorphism*.

Definition 1.15 (Epimorphism). If $\forall g_1, g_2$ the equation

$$g_1 \circ f = g_2 \circ f$$

leads to

$$g_1 = g_2$$

then f is called *epimorphism*.

Definition 1.16 (Isomorphism). A **Morphism** $f : a \rightarrow b$ is called *isomorphism* if $\exists g : b \rightarrow a$ such that $f \circ g = \mathbf{1}_{a \rightarrow a}$ and $g \circ f = \mathbf{1}_{b \rightarrow b}$. If there is an isomorphism f between objects a and b then it is denoted as $a \cong_f b$.

Remark 1.17 (Isomorphism). There are can be many different **Isomorphisms** between 2 **Objects**.

If there is an unique isomorphism between 2 objects then the objects can be treated as the same object.

1.1.3 Category

Definition 1.18 (Category). A category \mathbf{C} consists of

- **Class** of **Objects** $\text{ob}(\mathbf{C})$

Figure 1.3: Category \mathbf{C} . It consists of 4 objects $\text{ob}(\mathbf{C}) = \{a, b, c, d\}$ and 7 morphisms $\text{ob}(\mathbf{C}) = \{f, g, h = f \circ g, 1_{a \rightarrow a}, 1_{b \rightarrow b}, 1_{c \rightarrow c}, 1_{d \rightarrow d}\}$

- **Class of Morphisms** $\text{hom}(\mathbf{C})$ defined for $\text{ob}(\mathbf{C})$, i.e. each morphism f_{ab} from $\text{hom}(\mathbf{C})$ has both source a and target b from $\text{ob}(\mathbf{C})$

For any **Object** a there should be unique **Identity morphism** $1_{a \rightarrow a}$. Any morphism should satisfy **Composition** (**Axiom 1.8**) and **Associativity** (**Axiom 1.10**). See fig. 1.3

Definition 1.19 (Set of morphisms). The set of morphisms between objects a and b in the \mathbf{C} will be denoted as $\text{hom}_{\mathbf{C}}(a, b)$

The **Category** can be considered as a way to represent a structured data. **Morphisms** are the ones which form the structure.

Definition 1.20 (Opposite category). If \mathbf{C} is a **Category** then opposite (or dual) category \mathbf{C}^{op} is constructed in the following way: **Objects** are the same, but the **Morphisms** are inverted i.e. if $f \in \text{hom}(\mathbf{C})$ and $\text{dom } f = a, \text{cod } f = b$, then the corresponding morphism $f^{op} \in \text{hom}(\mathbf{C}^{op})$ has $\text{dom } f^{op} = b, \text{cod } f^{op} = a$ (see fig. 1.4)

Remark 1.21. Composition on \mathbf{C}^{op} As you can see from fig. 1.4 the **Composition** (**Axiom 1.8**) is reverted for **Opposite category**. If $f, g, h = f \circ g \in \text{hom}(\mathbf{C})$ then $f \circ g$ translated into $g^{op} \circ f^{op}$ in opposite category.

Definition 1.22 (Small category). A category \mathbf{C} is called *small* if both $\text{ob}(\mathbf{C})$ and $\text{hom}(\mathbf{C})$ are **Sets**

Definition 1.23 (Large category). A category \mathbf{C} is not **Small category** then it is called *large*. The example of large category is **Set category**

Figure 1.4: Opposite category C^{op} to the category from fig. 1.3 . It consists of 4 objects $\text{ob}(C^{op}) = \text{ob}(C) = \{a, b, c, d\}$ and 7 morphisms $\text{hom}(C^{op}) = \{f^{op}, g^{op}, h^{op} = g^{op} \circ f^{op}, 1_{a \rightarrow a}, 1_{b \rightarrow b}, 1_{c \rightarrow c}, 1_{d \rightarrow d}\}$

1.2 Set category example

There are several examples of categories that will also be used later

Definition 1.24 (Set). Set is a collection of distinct object. The objects are called the elements of the set.

Definition 1.25 (Binary relation). If A and B are 2 Sets then a subset of $A \times B$ is called binary relation R between the 2 sets, i.e. $R \subset A \times B$.

Definition 1.26 (Function). Function f is a special type of Binary relation. I.e. if A and B are 2 Sets then a subset of $A \times B$ is called function f between the 2 sets if $\forall a \in A \exists! b \in B$ such that $(a, b) \in f$. In other words function definition does not allow “multi value”.

Definition 1.27 (Cartesian product). If A and B are two sets then we can define a new set $A \times B = \{(a, b) | a \in A, b \in B\}$ that is called as the *cartesian product*.

Definition 1.28 (Set category). In the set category we consider a Set of Sets where Objects are the Sets and Morphisms are Functions between the sets.

The Identity morphism is trivial function such that $\forall x \in X : 1_{X \rightarrow X}(x) = x$.

In general case when we say Set category we assume the set of all sets. But the result is inconsistent because famous Russell’s paradox [16] can be

applied. To avoid such situations we consider a limitation that is applied on our construction, for instance ZFC [17]. If we apply the limitation we have that set of all sets is not a set itself and as result the **Set** category is a [Large category](#)

Remark 1.29 (Set vs Category). There is an interesting relation between sets and categories. In both we consider objects(sets) and relations between them(morphisms/functions).

In the set theory we can get info about functions by looking inside the objects(sets) aka use “microscope” [6]

Contrary in the category theory we initially don’t have any info about object internal structure but can get it using the relation between the objects i.e. using [Morphisms](#). In other words we can use “telescope” [6] there.

Definition 1.30 (Categorical approach). The description of a system via its communications we will call as *categorical approach*.

This description is contrary to an ordinary system description via its internal structure.

Definition 1.31 (Singleton). The *singleton* is a [Set](#) with only one element.

Example 1.32 (Domain). Given a function $f : X \rightarrow Y$, the set X is the domain. I.e. $\text{dom } f = X$

Example 1.33 (Codomain). Given a function $f : X \rightarrow Y$, the set Y is the codomain. I.e. $\text{cod } f = Y$

Definition 1.34 (Surjection). The function $f : X \rightarrow Y$ is surjective (or onto) if $\forall y \in Y, \exists x \in X$ such that $f(x) = y$ (see figs. 1.5 and 1.9).

Remark 1.35 (Surjection vs Epimorphism). [Surjection](#) and [Epimorphism](#) are related each other. Consider a non-surjective function $f : X \rightarrow Y' \subset Y$ (see fig. 1.6). One can conclude that there is not an [Epimorphism](#) because $\exists g_1 : Y' \rightarrow Y'$ and $g_2 : Y \rightarrow Y$ such that $g_1 \neq g_2$ because they operates on different [Domains](#) but from other hand $g_1(Y') = g_2(Y')$. For instance we can choose $g_1 = \mathbf{1}_{Y' \rightarrow Y'}$, $g_2 = \mathbf{1}_{Y \rightarrow Y}$. As soon as Y' is [Codomain](#) of f we always have $g_1(f(X)) = g_2(f(X))$.

As result we can say that an [Surjection](#) is a [Epimorphism](#) in the **Set** category. Moreover there is a proof [12] of that fact.

Definition 1.36 (Injection). The function $f : X \rightarrow Y$ is injective (or one-to-one function) if $\forall x_1, x_2 \in X$, such that $x_1 \neq x_2$ then $f(x_1) \neq f(x_2)$ (see figs. 1.7 and 1.9).

Figure 1.5: A surjective (non-injective) function from domain X to codomain Y

Figure 1.6: A non-surjective function f from domain X to codomain $Y' \subset Y$. $\exists g_1 : Y' \rightarrow Y', g_2 : Y \rightarrow Y$ such that $g_1(Y') = g_2(Y')$, but as soon as $Y' \neq Y$ we have $g_1 \neq g_2$. Using the fact that Y' is codomain of f we got $g_1 \circ f = g_2 \circ f$. I.e. the function f is not epimorphism.

Figure 1.7: An injective (non-surjective) function from domain X to codomain Y

Figure 1.8: A non-injective function f from domain X to codomain Y . $\exists g_1 : A \rightarrow X, g_2 : B \rightarrow X$ such that $g_1 \neq g_2$ but $f \circ g_1 = f \circ g_2$. I.e. the function f is not monomorphism.

Figure 1.9: An injective and surjective function (bijection)

Remark 1.37 (Injection vs Monomorphism). [Injection](#) and [Monomorphism](#) are related each other. Consider a non-injective function $f : X \rightarrow Y$ (see fig. 1.8). One can conclude that it is not monomorphism because $\exists g_1, g_2$ such that $g_1 \neq g_2$ and $f(g_1(a_1)) = y_3 = f(g_2(b_1))$.

As result we can say that an [Injection](#) is a [Monomorphism](#) in **Set** category. Moreover there is a proof [11] of that fact.

Definition 1.38 (Bijection). The function $f : X \rightarrow Y$ is bijective (or one-to-one correspondence) if it is an [Injection](#) and a [Surjection](#) (see fig. 1.9).

There is a question what is the categorical analog of a single [Set](#). Main characteristic of a category is a structure but the set by definition does not

have a structure. Which category does not have any structure? The answer is [Discrete category](#).

Definition 1.39 (Discrete category). Discrete category is a [Category](#) where [Morphisms](#) are only [Identity morphisms](#).

1.3 Programming languages examples

In the programming languages we consider types as [Objects](#) and functions as [Morphisms](#). The critical requirements for such consideration is that the functions have to be pure functions (without side effects). This requirement mainly is satisfied by functional languages such as Haskell and Scala. From other side the functional languages use lazy evaluation to improve their performance. The laziness can also make category theory axiom invalid (see [Haskell lazy evaluation](#) ([Remark 1.45](#))).

Strictly speaking neither Haskell (pure functional language) nor C++ can be considered as a category in general. For the first approximation a functional language (Haskell, Scala) can be considered as a category if we avoid to use functions with side effects (mainly for Scala) and use strict (for both Haskell and Scala) evaluations. Take the fact into consideration and define categories for 3 languages

Definition 1.40 (**Hask** category). The objects in the **Hask** category are Haskell types and morphisms are functions

Definition 1.41 (Pure function). The function is pure if it's execution give the same results independently from the environment.

Definition 1.42 (**Scala** category). The objects in the **Scala** category are Scala types and morphisms are functions. We don't define functions that have a state in the category. I.e. the functions are [Pure functions](#).

Definition 1.43 (**C++** category). The objects in the **C++** category are Scala types and morphisms are functions. We don't define functions that have a state in the category. I.e. the functions are [Pure functions](#).

In any case we can construct a simple toy category that can be easy implemented in any language. Particularly we will look into category with 3 objects that are types: Int, Bool, String. There are also several functions between them (see [fig. 1.10](#)).

Figure 1.10: Programming language category example. Objects are types: Int, Bool, String. Morphisms are several functions

1.3.1 Hask toy category

Example 1.44 (Hask toy category). Types in Haskell are considered as **Objects**. Functions are considered as **Morphisms**. We are going to implement **Category** from fig. 1.10.

The function `isEven` converts `Int` type into `Bool`.

```
isEven :: Int -> Bool
isEven x = x `mod` 2 == 0
```

There is also **Identity morphism** that is defined as follows

```
id :: a -> a
id x = x
```

If we have an additional function

```
stringLength :: String -> Int
stringLength x = length x
```

then we can create a **Composition** (Axiom 1.8)

```
isStringLengthEven :: String -> Bool
isStringLengthEven = isEven . stringLength
```

Remark 1.45 (Haskell lazy evaluation). Each Haskell type has a special value \perp . The fact that the value and lazy evaluations are part of the language, make several category law invalid, for instance [Identity morphism](#) behaviour become invalid in specific cases:

The following code

```
seq undefined True
```

produces *undefined* But the following

```
seq (id.undefined) True
seq (undefined.id) True
```

produces *True* in both cases. As result we have (we cannot compare compare functions in Haskell, but if we could we can get the following)

```
id . undefined /= undefined
undefined . id /= undefined,
```

i.e. [\(1.1\)](#) and [\(1.2\)](#) are not satisfied.

1.3.2 C++ toy category

Example 1.46 (C++ toy category). We will use the same trick as in [Hask toy category](#) ([Example 1.44](#)) and will assume types in C++ as [Objects](#), functions as [Morphisms](#). We also are going to implement [Category](#) from [fig. 1.10](#).

We also define 2 functions:

```
auto isEven = [](int x) {
    return x % 2 == 0;
};

auto stringLength = [](std::string s) {
    return static_cast<int>(s.size());
};
```

Composition can be defined as follows:

```
// h = g . f
template <typename A, typename B>
auto compose(A g, B f) {
    auto h = [f, g](auto a) {
        auto b = f(a);
```

```

    auto c = g(b);
    return c;
};
return h;
};

```

The [Identity morphism](#):

```

auto id = [](auto x) { return x; };

```

The usage examples are the following:

```

auto isStringLengthEven = compose<>(isEven, stringLength);

auto isStringLengthEvenL = compose<>(id, isStringLengthEven);

auto isStringLengthEvenR = compose<>(isStringLengthEven, id);

```

Such construction will always provides us the category as soon as we use pure function (functions without effects).

1.3.3 Scala toy category

Example 1.47 (Scala toy category). We will use the same trick as in [Hask toy category](#) ([Example 1.44](#)) and will assume types in Scala as [Objects](#), functions as [Morphisms](#). We also are going to implement [Category](#) from [fig. 1.10](#).

```

object Category {
  def id[A]: A => A = a => a
  def compose[A, B, C](g: B => C, f: A => B):
    A => C = g compose f

  val isEven = (i: Int) => i % 2 == 0
  val stringLength = (s: String) => s.length
  val isStringLengthEven = (s: String) =>
    compose(isEven, stringLength)(s)
}

```

The usage example is below

```

class CategorySpec extends Properties("Category") {
  import Category._
}

```

```

import Prop.forAll

property("composition") = forAll { (s: String) =>
  isStringLengthEven(s) == isEven(stringLength(s))
}

property("right id") = forAll { (i: Int) =>
  isEven(i) == compose(isEven, id[Int])(i)
}

property("left id") = forAll { (i: Int) =>
  isEven(i) == compose(id[Boolean], isEven)(i)
}
}

```

1.4 Quantum mechanics examples

The most critical property of quantum system is the superposition principle. The **Set category** cannot be used for it because it does not satisfied the principle. but a simple modification of the **Set** category does.

Definition 1.48 (**Rel** category). We will consider a set of sets (same as **Set category**) i.e. **Sets** as **Objects**. Instead of **Functions** we will use **Binary relations** as **Morphisms**.

The **Rel** category is similar to the finite dimensional Hilber space especially because it assumes some kind of superposition. Really consider **Rel** - the **Rel** category. $X, Y \in \text{ob}(\mathbf{Rel})$ - 2 sets which consists of different elements. Let $f : X \rightarrow Y$ - **Morphism**. Each element $x \in X$ is mapped to a subset $Y' \subset Y$. The Y' can be **Singleton** (in this case no differences with **Set category**) but there can be a situation when Y' consists of several elements. In the case we will get some kind of superposition that is analogiest to quantum systems.

In the quantum mechanics we say about Hilber spaces.

Definition 1.49 (Hilbert space). The Hilbert space is a complex vector space with an inner product as a complex number (\mathbb{C}).

Later we will consider only finite dimensional Hilber spaces. We will denote a Hilber space of dimensional n as \mathcal{H}_n . Obviously $\mathcal{H}_1 = \mathbb{C}$.

Definition 1.50 (Dual space). Each Hilber space \mathcal{H} has an associated with it dual space \mathcal{H}^* that consists of linear functionals

Example 1.51 (Dirac notation). Consider a ket-vector $|\psi\rangle \in \mathcal{H}$. Then the corresponding vector from [Dual space](#) is called bra-vector $\langle\psi| \in \mathcal{H}^*$. From the definition of dual space the bra-vector is a linear functional i.e.

$$\langle\psi| : \mathcal{H} \rightarrow \mathbb{C},$$

$\forall |\phi\rangle \in \mathcal{H}$ we have $\langle\psi|(|\phi\rangle) = (|\psi\rangle, |\phi\rangle)$ - inner product that is often written as $\langle\psi|\phi\rangle$.

The transformation between 2 [Hilbert spaces](#) that preserves the structure is called linear map or linear transformations.

Definition 1.52 (Linear map). The linear map between 2 [Hilbert spaces](#) \mathcal{A} and \mathcal{B} is a mapping $f : \mathcal{A} \rightarrow \mathcal{B}$ that preserves additions

$$f(a_1 + a_2) = f(a_1) + f(a_2),$$

and scalar multiplications:

$$f(c \cdot a) = c \cdot f(a)$$

where $a, a_{1,2} \in \mathcal{A}$ and $f(a), f(a_{1,2}) \in \mathcal{B}$.

Remark 1.53 (Linear map). Note that [Linear map](#) does not preserve inner product. TBD (verify the statement ???)

If we want to combine 2 Hilbert spaces into one we use a notion of direct sum.

Definition 1.54 (Direct sum of Hilbert spaces). Let \mathcal{A}, \mathcal{B} are 2 Hilbert spaces. The direct sum $\mathcal{A} \oplus \mathcal{B}$ is defined as follows

$$\mathcal{A} \oplus \mathcal{B} = \{a \oplus b | a \in \mathcal{A}, b \in \mathcal{B}\}.$$

The inner product is defined as follows

$$\langle a_1 \oplus b_1 | a_2 \oplus b_2 \rangle = \langle a_1 | a_2 \rangle + \langle b_1 | b_2 \rangle.$$

Definition 1.55 (**FdHilb** category). Most common case in quantum mechanics is the case of quantum states in the finite dimensional Hilbert space. We can consider the set of all finite dimensional Hilbert spaces as a category. The [Objects](#) in the category are finite dimensional [Hilbert spaces](#) and [Morphisms](#) are [Linear maps](#). The category is denoted as **FdHilb**. It is very similar to [Rel category](#). The brief relation is described in the table [1.1](#).

	Set	Rel	FdHilb
Object	Set	Set	finite dimensional Hilbert space
Morphism	Function	Binary relation	Linear map
Initial object	empty set	empty set	trivial Hilbert space of dimensional 0
Terminal object	Singleton	Singleton	\mathbb{C}
Product	Cartesian product	Cartesian product	Direct sum of Hilber spaces
Sum	Sum (Example 2.15)	Sum (Example 2.15)	Direct sum of Hilber spaces

Table 1.1: Relations between **Set**, **Rel** and **FdHilb** categories

Example 1.56 (Rabi oscillations). For our example we consider a 2 level atom with states $|a\rangle$ - excited and $|b\rangle$ - ground. As soon as we consider a 2-level system we are in the 2 dimensional Hilbert space i.e. have only one **Object**. Lets call it as $|\psi\rangle$. The category in the example will be called as **Rabi**. I.e. $\text{ob}(\mathbf{Rabi}) = \mathcal{H}_2\{|\psi\rangle\}$.

The atom interacts with light beam of frequency $\omega = \omega_{ab}$. The state of the system is described by the following equation [18]:

$$|\psi\rangle = \cos \frac{\omega_R t}{2} |a\rangle - i \sin \frac{\omega_R t}{2} |b\rangle ,$$

where ω_R - Rabi frequency [18].

The interaction time t is fixed and corresponds to $\omega_R t = \pi$ i.e. the interaction can be described a linear operator \hat{L} .

There are 4 different states and as result 4 **Morphisms**:

$$\begin{aligned} |\psi\rangle_0 &= |a\rangle , \\ |\psi\rangle_1 &= \hat{L} |\psi\rangle_0 = -i |b\rangle , \\ |\psi\rangle_2 &= \hat{L}^2 |\psi\rangle_0 = -|a\rangle , \\ |\psi\rangle_3 &= \hat{L}^3 |\psi\rangle_0 = i |b\rangle , \end{aligned}$$

Figure 1.11: Rabi oscillations as a category **Rabi**

Chapter 2

Objects and morphisms

2.1 Equality

The important question is how can we decide whenever an object/morphism is equal to another object/morphism? The trivial answer is possible if an **Object** is a **Set**. In the case we can say that 2 objects are equal if they contain the equivalent collection of elements. Unfortunately we cannot do the same trick for categorical **Objects** as soon as they don't have any internal structure but can use a **Categorical approach** (see **Set vs Category** (Remark 1.29)): if we cannot use “microscope” lets use “telescope” and define the equality of objects and morphisms of a category **C** in the terms of whole $\text{hom}(\mathbf{C})$.

Definition 2.1 (Objects equality). Two **Objects** a and b in **Category C** are equal if there exists an unique **Isomorphism** $a \cong_f b$. This also means that also exist unique isomorphism $b \cong_g a$. These two **Morphisms** (f and g) are related each other via the following equations: $f \circ g = \mathbf{1}_{a \rightarrow a}$ and $g \circ f = \mathbf{1}_{b \rightarrow b}$.

Unlike **Functions** between **Sets** we don't have any additional info ¹ about **Morphisms** except category theory axioms which the morphisms satisfy [2]. This leads us to the following definition of morphisms equality:

Definition 2.2 (Morphisms equality). Two **Morphisms** f and g in **Category C** are equal if the equality can be derived from the base axioms:

- **Composition** (Axiom 1.8)
- **Associativity** (Axiom 1.10)
- **Identity morphism**: (1.1), (1.2)

¹ for instance info about sets internals. i.e. which elements of the sets are connected by the considered functions

or [Commutative diagrams](#) which postulate the equality.

As an example lets proof the following theorem

Theorem 2.3 (Identity is unique). *The [Identity morphism](#) is unique.*

Proof. Consider an [Object](#) a and it's [Identity morphism](#) $\mathbf{1}_{a \rightarrow a}$. Let $\exists f : a \rightarrow a$ such that f is also identity. In the case (1.1) for f as identity gives

$$f \circ \mathbf{1}_{a \rightarrow a} = \mathbf{1}_{a \rightarrow a}.$$

From other side (1.2) for $\mathbf{1}_{a \rightarrow a}$ satisfied

$$f \circ \mathbf{1}_{a \rightarrow a} = f$$

i.e.

$$f = f \circ \mathbf{1}_{a \rightarrow a} = \mathbf{1}_{a \rightarrow a}$$

or $f = \mathbf{1}_{a \rightarrow a}$. □

2.2 Initial and terminal objects

Definition 2.4 (Initial object). Let \mathbf{C} is a [Category](#), the [Object](#) $i \in \text{ob}(\mathbf{C})$ is called *initial object* if $\forall x \in \text{ob}(\mathbf{C}) \exists ! f_x : i \rightarrow x \in \text{hom}(\mathbf{C})$.

Example 2.5 (Initial object). [\[Set\]](#) Note that there is only one function from empty set to any other sets [\[10\]](#) that makes the empty set as the [Initial object](#) in [Set category](#).

Definition 2.6 (Terminal object). Let \mathbf{C} is a [Category](#), the [Object](#) $t \in \text{ob}(\mathbf{C})$ is called *terminal object* if $\forall x \in \text{ob}(\mathbf{C}) \exists ! g_x : x \rightarrow t \in \text{hom}(\mathbf{C})$.

Example 2.7 (Terminal object). [\[Set\]](#) [Terminal object](#) in [Set category](#) is a set with one element i.e [Singleton](#).

As you can see the initial and terminal objects are opposite each other. I.e. if i is an [Initial object](#) in \mathbf{C} then it will be [Terminal object](#) in the [Opposite category](#) \mathbf{C}^{op} .

Theorem 2.8 (Initial object is unique). *Let \mathbf{C} is a category and $i, i' \in \text{ob}(\mathbf{C})$ two [Initial objects](#) then there exists an unique [Isomorphism](#) $u : i \rightarrow i'$ (see [Objects equality](#))*

Figure 2.1: Commutative diagram for initial object uniqueness proof

Figure 2.2: Commutative diagram for terminal object uniqueness proof

Proof. Consider the following [Commutative diagram](#) (see fig. 2.1). As soon as i initial object $\exists! u : i \rightarrow i'$. From other side i' is also initial object and therefore $\exists! u^{-1} : i' \rightarrow i$. Combining them together via composition we can get $u^{-1} \circ u : i \rightarrow i$ and $u \circ u^{-1} : i' \rightarrow i'$. From the fact that i is initial object one can get that there exists only one morphism $1_{i \rightarrow i} : i \rightarrow i$. The same is the truth for i' . Therefore $u^{-1} \circ u = 1_{i \rightarrow i}$ and $u \circ u^{-1} = 1_{i' \rightarrow i'}$. These complete the commutative diagram build and finishes the proof. \square

Theorem 2.9 (Terminal object is unique). *Let \mathbf{C} is a category and $t, t' \in \text{ob}(\mathbf{C})$ two [Terminal objects](#) then there exists an unique [Isomorphism](#) $v : t' \rightarrow t$ (see [Objects equality](#))*

Proof. Just got to the [Opposite category](#) and revert arrows in fig. 2.1. The result shown on fig. 2.2 and it proofs the theorem statement. \square

Example 2.10 (Toy example). In our toy example fig. 1.10 the type `String` is [Initial object](#) and type `Bool` is the [Terminal object](#).

Figure 2.3: Product $c = c_1 \times c_2$. $\forall c, \exists! h \in \text{hom}(\mathbf{C}) : \pi'_1 = \pi_1 \circ h, \pi'_2 = \pi_2 \circ h$.

2.3 Product and sum

The pair of 2 objects is defined via the universal property in the following way:

Definition 2.11 (Product). Let we have a category \mathbf{C} and $c_1, c_2 \in \text{ob}(\mathbf{C})$ -two **Objects** then the product of the objects c_1, c_2 is another object in \mathbf{C} $c = c_1 \times c_2$ with 2 **Morphisms** π_1, π_2 such that $c_1 = \pi_1(c), c_2 = \pi_2(c)$ and the following universal property is satisfied: $\forall c' \in \text{ob}(\mathbf{C})$ and morphisms $\pi'_1 : c' \rightarrow c_1, \pi'_2 : c' \rightarrow c_2$, exists unique morphism h such that the following diagram (see fig. 2.3) commutes, i.e. $\pi'_1 = \pi_1 \circ h, \pi'_2 = \pi_2 \circ h$. In other words h factorizes $\pi'_{1,2}$.

Example 2.12 (Product). **[Set]** The **Product** of two sets A and B in **Set category** is defined as a **Cartesian product**: $A \times B = \{(a, b) | a \in A, b \in B\}$.

If we invert arrows in **Product** we will got another object definition that is called sum

Definition 2.13 (Sum). Let we have a category \mathbf{C} and $c_1, c_2 \in \text{ob}(\mathbf{C})$ -two **Objects** then the sum of the objects c_1, c_2 is another object in \mathbf{C} $c = c_1 \oplus c_2$ with 2 **Morphisms** i_1, i_2 such that $c = i_1(c_1), c = i_2(c_2)$ and the following universal property is satisfied: $\forall c' \in \text{ob}(\mathbf{C})$ and morphisms $i'_1 : c_1 \rightarrow c', i'_2 : c_2 \rightarrow c'$, exists unique morphism h such that the following diagram (see fig. 2.4) commutes, i.e. $i'_1 = h \circ i_1, i'_2 = h \circ i_2$. In other words h factorizes $i'_{1,2}$.

Definition 2.14 (Disjoint union). Let $\{A_i : i \in I\}$ be a family of sets indexed by I . The *disjoint union* [14] of this family is the set

$$\sqcup_{i \in I} A_i = \cup_{i \in I} \{(x, i) : x \in A_i\}.$$

The elements of the disjoint union are ordered pairs (x, i) . Here i serves as an auxiliary index that indicates which A_i the element x came from.

Figure 2.4: Sum $c = c_1 \oplus c_2$. $\forall c, \exists! h \in \text{hom}(\mathbf{C}) : i_1' = h \circ i_1, i_2' = h \circ i_2$.

Figure 2.5: Product of morphisms.

Example 2.15 (Sum). **[Set]** The **Sum** of two sets A and B in **Set** category is defined as **Disjoint union**.

The **Product** of objects will provide also a definition for product of morphisms

Definition 2.16 (Product of morphisms). Let \mathbf{C} is a category and $a, a' \in \text{ob}(\mathbf{C})$ and $b, b' \in \text{ob}(\mathbf{C})$ are 2 pairs of **Objects** that admit definition 2.11. Consider 2 morphisms that connects the objects: $f : a \rightarrow b, f' : a' \rightarrow b'$ then we can create a new unique morphism that connects the products: $f \times f' : a \times a' \rightarrow b \times b'$ and makes the diagram commute (see fig. 2.5).

2.4 Category as a monoid

Consider the following definition from abstract algebra

Definition 2.17 (Monoid). The set of elements M with defined binary operation \circ we will call as a monoid if the following conditions are satisfied.

1. Closure: $\forall a, b \in M : a \circ b \in M$
2. Associativity: $\forall a, b, c \in M : a \circ (b \circ c) = (a \circ b) \circ c$

3. Identity element: $\exists e \in M$ such that $\forall a \in M: e \circ a = a \circ e = a$

We can consider 2 **Monoids**. The first one has **Product** as the binary operation and **Terminal object** as the identity element. As result we just got an analog of multiplication in the category theory. This is why the terminal object is often denoted as **1** and the operation is called as the product.

Another one is additional **Monoid** that has **Initial object** as the identity element and the **Sum** as the binary operation. The initial object in that case is often denoted as **0**. I.e. we can see a direct connection with addition in algebra.

If we do such consideration then we can make a step forward and look at the distributive law that sum and multiplication satisfy.

Definition 2.18 (Distributive category). A category **C** is *distributive* if [15] it has finite **Products** and **Sums** such that $\forall a, b, c \in \text{ob}(\mathbf{C})$:

$$a \times b \oplus a \times c \cong a \times (b \oplus c)$$

and

$$a \times 0 \cong 0$$

where **0** is the **Initial object**.

Example 2.19 (Distributive category). **Set category** is an example [15] of **Distributive category**

From other hand not all categories which have both product and sum are distributive. One of such example is a category of all groups [15] **Grp** where groups are considered as objects and group homomorphisms as morphisms.

2.5 Exponential

We are going to talk about functions (aka morphisms) as **Objects**.

Example 2.20 (Hom set). Consider 2 sets A and B the set of functions between the 2 sets form a new set that is called as *Hom-set* and denoted as $A \rightarrow B$. Thus if $A, B \in \text{ob}(\mathbf{Set})$ then the Hom-set will also $A \rightarrow B \in \text{ob}(\mathbf{Set})$.

The construction of **Hom set** (Example 2.20) is applied to **Set category** but not to an arbitrary category because the Hom-set is a set and therefore the object in the **Set** category. I.e. if **C** is a category and $a, b \in \text{ob}(\mathbf{C})$ then the Hom-set $a \rightarrow b \in \text{ob}(\mathbf{Set})$ but we now want to construct something like to the Home-set but that is an object in **C**. This will be called as the function object. We will use the universal construction for the object definition.

Figure 2.6: Exponential object

Definition 2.21 (Exponential). Let \mathbf{C} is a category and $z, y \in \text{ob}(\mathbf{C})$. We also assume that \mathbf{C} allows all **Products** with y , i.e. $\forall z' \in \text{ob}(\mathbf{C}), \exists z' \times y$. An object z^y together with a **Morphism** $e : z^y \times y \rightarrow z$ is an *exponential object* if $\forall e' \in \text{hom}(\mathbf{C})$ and $\forall z' \in \text{ob}(\mathbf{C})$ exists an unique morphism $h : z' \rightarrow z^y$ such that the **Commutative diagram** shown in fig. 2.6 commutes:

$$e' = e \circ (h \times \mathbf{1}_{y \rightarrow y})$$

Example 2.22 (Exponential). [**Set**] Lets look at the **Exponential** in **Set**. We want to show that the object corresponds to the function. Really if we want to define a function $f : X \rightarrow Y$ then we should look at the **Hom set** (**Example 2.20**) $F = X \rightarrow Y$. $f \in F$ - is an element of the Hom-set. For the function application we have to take the argument $x \in X$ and the function we want to apply $f \in F$. Then we construct the pair $(f, x) \in F \times X$. For the function application we have to call a **Morphism** $e : F \times X \rightarrow Z$.² I.e. the application $e(f, x)$ gives us $e(f, x) = y \in Y$ - the function value.

Definition 2.23 (Cartesian closed category). If a category \mathbf{C} satisfies the following conditions then it is called *Cartesian closed category*

1. It has **Terminal object**
2. $\forall a, b \in \text{ob}(\mathbf{C})$ exists **Product** $a \times b \in \text{ob}(\mathbf{C})$.
3. $\forall a, b \in \text{ob}(\mathbf{C})$ exists **Exponential** $a^b \in \text{ob}(\mathbf{C})$

Theorem 2.24 (Cartesian closed category). *If \mathbf{C} is a **Cartesian closed category** with finite **Sum** then it is a **Distributive category**.*

Proof. TBD

□

² e from the word “eval”

2.6 Type algebra and Curry-Howard-Lambek correspondence

There is an interesting correspondence between computer programs and mathematical proofs. First of all consider a category of proofs

2.6.1 Proof category

Definition 2.25 (Proposition). *Proposition* is a statement that either true or false.

There are 2 main propositions

Definition 2.26 (True). A true statement is one that is correct, either in all cases or at least in the sample case [13].

and

Definition 2.27 (False). A false statement is one that is not correct [13].

Example 2.28 (Proposition). There is an example of correct (true) proposition

$$\forall n \in \mathbb{R} : n^2 \geq 0$$

There is an example of incorrect (false) proposition

$$\forall n \in \mathbb{C} : n^2 \geq 0,$$

for instance $i \in \mathbb{C}$ gives $i^2 = -1$.

Definition 2.29 (Implication). An *implication* is a [Proposition](#) of the form $P \implies Q$ i.e. if P then Q [5].

The main logical deduction rule is the following

Definition 2.30 (Modus ponens). If P is true and $P \implies Q$ is true then Q is also true. The rule is often written as [5]

$$\frac{\begin{array}{c} P \\ P \implies Q \end{array}}{Q}$$

where if statements above the line are true then the statement below the line is also true.

Definition 2.31 (Proof). *Proof* is a verification [5] of a [Proposition](#) by a chain of logical deduction from a base set of axioms.

Propositions can be combined into new propositions via the following logical operations

Definition 2.32 (Conjunction). Conjunction or logical AND is the operation with following rules

a	b	$a \wedge b$
True	True	True
True	False	False
False	True	False
False	False	False

Table 2.1: Conjunction

Definition 2.33 (Disjunction). Conjunction or logical OR is the operation with following rules

a	b	$a \vee b$
True	True	True
True	False	True
False	True	True
False	False	False

Table 2.2: Disjunction

Operations in Boolean logic follow the distributive law:

$$a \wedge (b \vee c) = (a \wedge b) \vee (a \wedge c)$$

i.e. the operation \wedge corresponds to multiplication and \vee to sum. Therefore the **Proof** can be considered as a [Distributive category](#).

Definition 2.34 (**Proof** category). The **Proof** category is a category where [Propositions](#) are [Objects](#) and [Proofs](#) are [Morphisms](#). I.e. proofs are used as connectors between different propositions.

Consider different objects and constructions of the proof (logic) theory from the categorical point of view

Example 2.35 (Initial object). [**Proof**] The *false* statement can be considered as the initial object because for any other statement exists only one proof from the false statement to that one.

Example 2.36 (Terminal object). [**Proof**] The *true* statement can be considered as the terminal object

Example 2.37 (Product). [**Proof**] **Conjunction** can be considered as **Product** in **Proof** category.

Example 2.38 (Sum). [**Proof**] **Disjunction** can be considered as **Sum** in **Proof** category.

Thus we can declare the following correspondence (see table 2.3) between logic proofs and **Cartesian closed category** and therefore also between programming languages.

Proof category	Programming language	Cartesian closed category
Proposition/Implication	Type	Object
Proof	Function type	Exponential
Conjunction	Product type	Product
Disjunction	Sum type	Sum
True	unit type	Terminal object
False	botom type	Initial object

Table 2.3: Relation between logic proofs and programming languages

2.6.2 Hask category

Example 2.39 (Initial object). [**Hask**] If we avoid lazy evaluations in Haskell (see **Haskell lazy evaluation** (Remark 1.45)) then we can found several types as candidates for initial and terminal object in Haskell. **Initial object** in **Hask** category is a type without values

```
data Void
```

i.e. you cannot construct a object of the type.

There is only one function from the initial object:

```
absurd :: Void -> a
```

The function is called absurd because it does absurd action. Nobody can proof that it does not exist. For the existence proof the following absurd argument can be used: “Just provide me an object type **Void** and I will provide you the result of evaluation”.

There is no function in opposite direction because it would had been used for the **Void** object creation.

Example 2.40 (Terminal object). [Hask] Terminal object (unit) in **Hask** category keeps only one element

```
data () = ()
```

i.e. you can create only one element of the type. You can use the following function for the creation:

```
unit :: a -> ()
unit _ = ()
```

Example 2.41 (Product). [Hask] The **Product** in **Hask** category keeps a pair and the constructor defined as follows

```
(,) :: a -> b -> (a, b)
(,) x y = (x, y)
```

There are 2 projectors:

```
fst :: (a, b) -> a
fst (x, _) = x
snd :: (a, b) -> b
snd (_, y) = y
```

Example 2.42 (Sum). [Hask] The **Sum** in **Hask** category defined as follows

```
data Either a b = Left a | Right b
```

The typical usage is via pattern matching for instance

```
factor :: (a -> c) -> (b -> c) -> Either a b -> c
factor f _ (Left x) = f x
factor _ g (Right y) = g y
```

Example 2.43 (Distributive category). [Hask] As soon as **Hask** is a **Cartesian closed category** then by theorem 2.24 it is a **Distributive category** i.e. one can conclude that

```
(a, Either b c)
```

is the same to

```
Either (a, b) (a, c)
```

Example 2.44 (Exponential). [Hask] It's not surprisingly that the **Exponential** in **Hask** is a function object i.e. b^a can be written as **a -> b**.

Example 2.45 (Type algebra). example 2.44 gives interesting results with types manipulations. For instance the type a^{b+c} can be written as

```
Either b c -> a
```

for the function we should have both functions $b \rightarrow a$ and $b \rightarrow c$. I.e. the code is equivalent to the following one

```
(b -> a, c -> a)
```

These transformations correspond to the following simple algebraic equation

$$a^{b+c} = a^b a^c.$$

This is also called as *type algebra*.

2.6.3 C++ category

Example 2.46 (Initial object). [C++] In C++ exists a special type that does not hold any values and as result cannot be created: `void`. You cannot create an object of that type i.e. you will get a compiler error if you try.

Example 2.47 (Terminal object). [C++] C++ 17 introduced a special type that keeps only one value - `std::monostate`:

```
namespace std {
    struct monostate {};
}
```

Example 2.48 (Product). [C++] The `Product` in `C++ category` keeps a pair and the constructor defined as follows

```
namespace std {
    template< class A, class B > struct pair {
        A first;
        B second;
    };
}
```

There is a simple usage example

```
std::pair<int, bool> p(0, false);

std::cout << "First projector: " << p.first << std::endl;
std::cout << "Second projector: " << p.second << std::endl;
```

Really any `struct` or `class` can be considered as a product.

Example 2.49 (Sum). [C++] If we consider `Objects` as types then `Sum` is an object that can be either one or another type. The corresponding C/C++ construction that provides an ability to keep one of two types is `union`.

C++17 suggests `std::variant` as a safe replacement for `union`. The example of the `factor` function is below

```
template <typename A, typename B, typename C, typename D>
auto factor(A f, B g, const std::variant<C, D>& either) {
    try {
        return f(std::get<C>(either));
    }
    catch(...) {
        return g(std::get<D>(either));
    }
};
```

The simple usage as follows:

```
std::variant<std::string, int> var = std::string("abc");
std::cout << "String length:" <<
factor<>(stringLength, id, var) << std::endl;
var = 4;
std::cout << "id(int):" <<
factor<>(stringLength, id, var) << std::endl;
```

TBD

2.6.4 Scala category

Example 2.50 (Initial object). [Scala] We used a same trick as for `Initial object` (Example 2.39) in `Hask category` and define `Initial object` in `Scala category` as a type without values

```
sealed trait Void
```

i.e. you cannot construct a object of the type.

Example 2.51 (Terminal object). [Scala] We used a same trick as for `Terminal object` (Example 2.40) in `Hask category` and define `Terminal object` in `Scala category` as a type with only one value

```
abstract final class Unit extends AnyVal
```

TBD i.e. you can create only one element of the type.

TBD

2.7 Quantum mechanics

Example 2.52 (Initial object). **[FdHilb]** We will use a Hilber space of dimensional 0 as the [Initial object](#). I.e. the set that does not have any states in it.

Example 2.53 (Terminal object). **[FdHilb]** We will use a Hilber space of dimensional 1 as the [Terminal object](#). I.e. the set of complex numbers \mathbb{C} .

Example 2.54 (Product). **[FdHilb]** The [Product](#) in **FdHilb** category is a [Direct sum of Hilber spaces](#).

Example 2.55 (Sum). **[FdHilb]** The [Sum](#) in **FdHilb** category is a [Direct sum of Hilber spaces](#).

TBD

Chapter 3

Functors

3.1 Definitions

Definition 3.1 (Functor). Let \mathbf{C} and \mathbf{D} are 2 categories. A mapping $F : \mathbf{C} \Rightarrow \mathbf{D}$ between the categories is called *functor* if it preserves the internal structure (see fig. 3.1):

- $\forall a_C \in \text{ob}(\mathbf{C}), \exists a_D \in \text{ob}(\mathbf{D})$ such that $a_D = F(a_C)$
- $\forall f_C \in \text{hom}(\mathbf{C}), \exists f_D \in \text{hom}(\mathbf{D})$ such that $\text{dom } f_D = F(\text{dom } f_C), \text{cod } f_D = F(\text{cod } f_C)$. We will use the following notation later: $f_D = F(f_C)$.
- $\forall f_C, g_C$ the following equation holds:

$$F(f_C \circ g_C) = F(f_C) \circ F(g_C) = f_D \circ g_D.$$

- $\forall x \in \text{ob}(\mathbf{C}) : F(1_{x \rightarrow x}) = 1_{F(x) \rightarrow F(x)}$.

Figure 3.1: Functor $F : \mathbf{C} \Rightarrow \mathbf{D}$ definition

Remark 3.2 (Functor). When we say that functor preserve internal structure we assume that the functor is not just mapping between **Objects** but also between **Morphisms**.

Thus functor is something that allows map one category into another. The initial category can be considered as a pattern thus the mapping is some kind of searching of the pattern inside another category.

Programming languages can be considered as a good platform for the functor examples. The functor can be defined in Haskell as follows ¹

Example 3.3 (Functor). [**Hask**]

```
class Functor f where
  fmap :: (a -> b) -> f a -> f b
```

The concrete example is the following

Example 3.4 (Maybe as a functor). [**Hask**] Lets show how the **Maybe** a type can be constructed from different **Functors** and as result show that the **Maybe** a is also a **Functor**.

```
data Maybe a = Nothing | Just a
-- This is equivalent to
data Maybe a = Either () (Identity a)
-- Either is a bifunctor and () == Const () a
-- Thus Maybe is a composition of 2 functors
```

In Scala it can be defined in the same way

Example 3.5 (Functor). [**Scala**]

```
trait Functor[F[_]] {
  def fmap[A, B](f: A => B): F[A] => F[B]
```

Definition 3.6 (Endofunctor). Let **C** is a **Category**. The **Functor** $E : \mathbf{C} \Rightarrow \mathbf{C}$ i.e. the functor from a category to the same category is called *endofunctor*.

Definition 3.7 (Identity functor). Let **C** is a **Category**. The **Functor** $1_{\mathbf{C} \Rightarrow \mathbf{C}} : \mathbf{C} \Rightarrow \mathbf{C}$ is called *identity functor* if for every object $a \in \text{ob}(\mathbf{C})$

$$1_{\mathbf{C} \Rightarrow \mathbf{C}}(a) = a$$

and for every **Morphism** $f \in \text{hom}(\mathbf{C})$

$$1_{\mathbf{C} \Rightarrow \mathbf{C}}(f) = f$$

¹the real definition is quite different from the current one

Remark 3.8 (Identity functor). First of all notice that [Identity functor](#) is an [Endofunctor](#).

There is difference between identity functor and [Identity morphism](#) because the first one has deal with both [Objects](#) and [Morphisms](#) while the second one with the objects only.

Definition 3.9 (Functor composition). If we have 3 categories $\mathbf{C}, \mathbf{D}, \mathbf{E}$ and 2 functors between them: $F : \mathbf{C} \Rightarrow \mathbf{D}$ and $G : \mathbf{D} \Rightarrow \mathbf{E}$ then we can construct a new functor $H : \mathbf{C} \Rightarrow \mathbf{E}$ that is called *functor composition* and denoted as $H = G \circ F$. TBD

3.2 Cat category

The [Functor composition](#) is associative by definition. Therefore [Identity functor](#) with the associative composition allow us to define a category where other categories are considered as objects and functors as morphisms:

Definition 3.10 (**Cat** category). The category of small categories (see [Small category](#)) denoted as **Cat** is the [Category](#) where objects are small categories and morphisms are [Functors](#) between them.

We can construct an extension of Cartesian product as follows

Definition 3.11 (Category Product). If we have 2 categories \mathbf{C} and \mathbf{D} then we can construct a new category $\mathbf{C} \times \mathbf{D}$ with the following components:

- [Objects](#) are the pairs (c, d) where $c \in \text{ob}(\mathbf{C})$ and $d \in \text{ob}(\mathbf{D})$
- [Morphisms](#) are the pair (f, g) where $f \in \text{hom}(\mathbf{C})$ and $g \in \text{hom}(\mathbf{D})$
- [Composition](#) ([Axiom 1.8](#)) is defined as follows $(f_1, g_1) \circ (f_2, g_2) = (f_1 \circ f_2, g_1 \circ g_2)$
- Identity is defined as follows: $\mathbf{1}_{\mathbf{C} \times \mathbf{D}} = (\mathbf{1}_{\mathbf{C}}, \mathbf{1}_{\mathbf{D}})$

Definition 3.12 (Terminal object in **Cat** category). Let consider Δ_c is a trivial functor from [Category](#) \mathbf{A} to category \mathbf{C} such that $\forall a \in \text{ob}(\mathbf{A}) : \Delta_c a = c$ -fixed object in \mathbf{C} and $\forall f \in \text{hom}(\mathbf{A}) : \Delta_c f = \mathbf{1}_{c \rightarrow c}$.

The good example can be found in **Hask** category.

Example 3.13 (Terminal object in **Cat** category). [**Hask**]

```
data Const c a = Const c
fmap :: (a -> b) -> Const c a -> Const c b
fmap f (Const c a) = Const c
```

3.3 Bifunctors

Definition 3.14 (Bifunctor). Bifunctor is a **Functor** whose **Domain** is a **Category Product**. I.e. if $\mathbf{C}_1, \mathbf{C}_2, \mathbf{D}$ are 3 categories then the **Functor** $F : \mathbf{C}_1 \times \mathbf{C}_2 \Rightarrow \mathbf{D}$ is called *bifunctor*.

Example 3.15 (Bifunctor). **[Set]** Lets A, B, C and D are sets and $f : A \rightarrow C, g : B \rightarrow D$ are two **Functions**. Then the **Cartesian product** with **Product of morphisms** form a **Bifunctor** \times .

Definition 3.16 (Contravariant functor). If we have categories \mathbf{C} and \mathbf{D} then the **Functor** $\mathbf{C}^{\text{op}} \Rightarrow \mathbf{D}$ is called *contravariant functor*.

Example 3.17 (Contravariant functor). **[Hask]** TBD

```
class Contravariant f where
  contramap :: (a -> b) -> f b -> f a
```

Definition 3.18 (Profunctor). If we have a category \mathbf{C} then the **Bifunctor** $\mathbf{C}^{\text{op}} \times \mathbf{C} \Rightarrow \mathbf{C}$ is called *profunctor*.

Example 3.19 (Profunctor). **[Hask]** TBD

```
class Profunctor p where
  dimap :: (a' -> a) -> ( b -> b' ) -> p a b -> p a' b'
  -- p a b == a -> b
  dimap f g h = g . h . f
```

Chapter 4

Natural transformation

Natural transformation is the most important part of the category theory. It provides a possibility to compare **Functors** via a standard tool.

4.1 Definitions

The natural transformation is not an easy concept compare other ones and requires some additional preparations before we can give the formal definition.

Consider 2 categories \mathbf{C}, \mathbf{D} and 2 **Functors** $F : \mathbf{C} \Rightarrow \mathbf{D}$ and $G : \mathbf{C} \Rightarrow \mathbf{D}$. If we have an **Object** $a \in \text{ob}(\mathbf{C})$ then it will be translated by different functors into different objects of category \mathbf{D} : $a_F = F(a), a_G = G(a) \in \text{ob}(\mathbf{D})$ (see fig. 4.1). There are 2 options possible

1. There is not any **Morphism** that connects a_F and a_G .
2. $\exists \alpha_a \in \text{hom}(a_F, a_G) \subset \text{hom}(\mathbf{D})$.

Figure 4.1: Natural transformation: object mapping

Figure 4.2: Natural transformation: morphisms mapping

Figure 4.3: Natural transformation: commutative diagram

We can of course to create an artificial morphism that connects the objects but if we use *natural* morphisms ¹ then we can get a special characteristic of the considered functors and categories. For instance if we have such morphisms then we can say that the considered functors are related each other. Opposite example if there are no such morphisms then the functors can be considered as unrelated each other.

The functor is not just the object mapping but also the morphisms mapping. If we have 2 objects a and b in the category \mathbf{C} then we potentially can have a morphism $f \in \text{hom}_{\mathbf{C}}(a, b)$. In this case the morphism is mapped by the functors F and G into 2 morphisms f_F and f_G in the category \mathbf{D} . As result we have 4 morphisms: $\alpha_a, \alpha_b, f_F, f_G \in \text{hom}(\mathbf{D})$. It is natural to impose additional conditions on the morphisms especially that they form a [Commutative diagram](#) (see fig. 4.3):

$$f_f \circ \alpha_b = \alpha_a \circ f_G.$$

¹the word natural means that already existent morphisms from category \mathbf{D} are used

Definition 4.1 (Natural transformation). Let F and G are 2 **Functors** from category \mathbf{C} to the category \mathbf{D} . The *natural transformation* is a set of **Morphisms** $\alpha \subset \text{hom}(\mathbf{D})$ which satisfy the following conditions:

- For every **Object** $a \in \text{ob}(\mathbf{C})$ $\exists \alpha_a \in \text{hom}(a_F, a_G)$ ² - **Morphism** in category \mathbf{D} . The morphism α_a is called the component of the natural transformation.
- For every morphism $f \in \text{hom}(\mathbf{C})$ that connects 2 objects a and b , i.e. $f \in \text{hom}_{\mathbf{C}}(a, b)$ the corresponding components of the natural transformation $\alpha_a, \alpha_b \in \alpha$ should satisfy the following conditions

$$f_G \circ \alpha_a = \alpha_b \circ f_F, \quad (4.1)$$

where $f_F = F(f), f_G = G(f)$. In other words the morphisms form a **Commutative diagram** shown on the fig. 4.3.

We use the following notation (arrow with a dot) for the natural transformation between functors F and G : $\alpha : F \dot{\rightarrow} G$.

4.2 Operations with natural transformations

Example 4.2 (**Fun** category). The functors can be considered as objects in a special category **Fun**. The morphisms in the category are **Natural transformations**.

To define a category we need to define composition operation that satisfied **Composition** (**Axiom 1.8**), identity morphism and verify **Associativity** (**Axiom 1.10**).

For the composition consider 2 **Natural transformations** α, β and consider how they act on an object $a \in \text{ob}(\mathbf{C})$ (see fig. 4.4). We always can construct the composition $\beta_a \circ \alpha_a$ i.e. we can define the composition of natural transformations α, β as $\beta \circ \alpha = \{\beta_a \circ \alpha_a | a \in \text{ob}(\mathbf{C})\}$.

The natural transformation is not just object mapping but also morphism mapping. We will require that all morphisms shown on fig. 4.5 commute. The composition defined in such way is called **Vertical composition**.

The functor category between categories \mathbf{C} and \mathbf{D} is denoted as $[\mathbf{C}, \mathbf{D}]$.

Definition 4.3 (Vertical composition). Let F, G, H are functors between categories \mathbf{C} and \mathbf{D} . Also we have $\alpha : F \dot{\rightarrow} G, \beta : G \dot{\rightarrow} H$ - natural transformations. We can compose the α and β as follows

$$\alpha \circ \beta : F \dot{\rightarrow} H.$$

² $a_F = F(a), a_G = G(a)$

Figure 4.4: Natural transformation vertical composition: object mapping

Figure 4.5: Natural transformation vertical composition: morphism mapping
- commutative diagram

This composition is called *vertical composition*.

Definition 4.4 (Horizontal composition). If we have 2 pairs of functors. The first one $F, G : \mathbf{C} \rightarrow \mathbf{D}$ and another one $J, K : \mathbf{D} \Rightarrow \mathbf{E}$. We also have a natural transformation between each pair: $\alpha : F \rightrightarrows G$ for the first one and $\beta : J \rightrightarrows K$ for the second one. We can create a new transformation

$$\alpha \star \beta : F \circ J \rightrightarrows G \circ K$$

that is called *horizontal composition*. Note that we use a special symbol \star for the composition.

Remark 4.5 (Bifunctor in category of functors). If we have the same pair of functors as in definition 4.4 then we can consider the functors as objects of 3 categories: $\mathcal{A} = [\mathbf{C}, \mathbf{D}]$, $\mathcal{B} = [\mathbf{D}, \mathbf{E}]$ and $\mathcal{C} = [\mathbf{C}, \mathbf{E}]$

Next we want to construct a Bifunctor $\otimes : \mathcal{A} \times \mathcal{B} \Rightarrow \mathcal{C}$ where for each pair of objects $F \in \text{ob}(\mathcal{A})$, $J \in \text{ob}(\mathcal{B})$ we got another object from \mathcal{C} . The used operation is an ordinary functor's composition. I.e.

$$\otimes : F \times G \rightarrow F \circ G \in \text{ob}(\mathcal{C}).$$

The bifunctor is not just a map for objects. There is also a map between morphisms. Thus if we have 2 Morphisms: $\alpha : F \rightarrow G$ and $\beta : J \rightarrow K$ then we can construct the following mapping

$$\otimes : \alpha \times \beta \rightarrow \alpha \star \beta \in \text{hom}(\mathcal{C}).$$

As result we have the introduced mapping \otimes as a bifunctor.

Definition 4.6 (Left whiskering). If we have 3 categories $\mathbf{B}, \mathbf{C}, \mathbf{D}$, Functors $F, G : \mathbf{C} \Rightarrow \mathbf{D}$, $H : \mathbf{B} \rightarrow \mathbf{C}$ and Natural transformation $\alpha : F \rightrightarrows G$ then we can construct a new natural transformations:

$$\alpha H : F \circ H \rightrightarrows G \circ H$$

that is called *left whiskering* of functor and natural transformation [9].

Definition 4.7 (Right whiskering). If we have 3 categories $\mathbf{C}, \mathbf{D}, \mathbf{E}$, Functors $F, G : \mathbf{C} \Rightarrow \mathbf{D}$, $H : \mathbf{D} \rightarrow \mathbf{E}$ and Natural transformation $\alpha : F \rightrightarrows G$ then we can construct a new natural transformations:

$$H\alpha : H \circ F \rightrightarrows H \circ G$$

that is called *right whiskering* of functor and natural transformation [9].

Definition 4.8 (Identity natural transformation). If $F : \mathbf{C} \Rightarrow \mathbf{D}$ is a **Functor** then we can define *identity natural transformation* $\mathbf{1}_{F \rightarrow F}$ that maps any **Object** $a \in \text{ob}(\mathbf{C})$ into **Identity morphism** $\mathbf{1}_{F(a) \rightarrow F(a)} \in \text{hom}(\mathbf{D})$.

Remark 4.9 (Whiskering). With **Identity natural transformation** we can redefine **Left whiskering** and **Right whiskering** via **Horizontal composition** as follows.

For left whiskering:

$$\alpha H = \alpha \star \mathbf{1}_{H \rightarrow H} \quad (4.2)$$

For right whiskering:

$$H\alpha = \mathbf{1}_{H \rightarrow H} \star \alpha \quad (4.3)$$

4.3 Polymorphism and natural transformation

Polymorphism plays a certain role in programming languages. Category theory provides several facts about polymorphic functions which are very important.

Definition 4.10 (Parametrically polymorphic function). Polymorphism is parametric if all function instances behave uniformly i.e. have the same realization. The functions which satisfy the parametric polymorphism requirements are parametrically polymorphic.

Definition 4.11 (Ad-hoc polymorphism). Polymorphism is parametric if the function instances can behave differently dependently on the type they are being instantiated with.

Theorem 4.12 (Reynolds). *Parametrically polymorphic functions are Natural transformations*

Proof. TBD □

4.3.1 Hask category

In Haskell most of functions are **Parametrically polymorphic functions**³.

Example 4.13 (Parametrically polymorphic function). **[Hask]** Consider the following function

```
safeHead :: [a] -> Maybe a
safeHead [] = Nothing
safeHead (x:xs) = Just x
```

³really in the run-time the functions are not **Parametrically polymorphic functions**

Figure 4.6: Haskell parametric polymorphism as a natural transformation

The function is parametrically polymorphic and by [Reynolds](#) ([Theorem 4.12](#)) is [Natural transformation](#) (see [fig. 4.6](#)).

Therefore from the definition of the natural transformation ([4.1](#)) we have `fmap f . safeHead = safeHead . fmap f`. I.e. it does not matter if we initially apply `fmap f` and then `safeHead` to the result or initially `safeHead` and then `fmap f`.

The statement can be verified directly. For empty list we have

```
fmap f . safeHead []
-- equivalent to
fmap f Nothing
-- equivalent to
Nothing
```

from other side

```
safeHead . fmap f []
-- equivalent to
safeHead []
-- equivalent to
Nothing
```

For a non empty list we have

```
fmap f . safeHead (x:xs)
-- equivalent to
fmap f (Just x)
```

```
-- equivalent to  
Just (f x)
```

from other side

```
safeHead . fmap f (x:xs)  
-- equivalent to  
safeHead (f x: fmap f xs )  
-- equivalent to  
Just ( f x )
```

Using the fact that `fmap f` is an expensive operation if it is applied to the list we can conclude that the second approach is more productive. Such transformation allows compiler to optimize the code. ⁴

⁴It is not directly applied to Haskell because it has lazy evaluation that can perform optimization before that one

Chapter 5

Monads

Monads are very important for pure functional programming languages such as Haskell. We will start with [Monoid](#) consideration, continue with the formal mathematical definition for monad and will finish with programming languages examples later.

5.1 Monoid in Set category

We are going to consider [Monoid](#) in the terms of Set theory and will try to give the definition that is based rather on morphisms than on internal set structure i.e. we will use [Categorical approach](#). Let M is a set and by the monoid definition (definition [2.17](#)) $\forall m_1, m_2 \in M$ we can define a new element of the set $\mu(m_1, m_2) \in M$. Later we will use the following notation for the μ :

$$\mu(m_1, m_2) \equiv m_1 \cdot m_2.$$

If the (M, \cdot) is monoid then the following 2 conditions have to be satisfied. The first one (associativity) declares that $\forall m_1, m_2, m_3 \in M$

$$m_1 \cdot (m_2 \cdot m_3) = (m_1 \cdot m_2) \cdot m_3.$$

The second one (identity presence) says that $\exists e \in M$ such that $\forall m \in M$:

$$m \cdot e = e \cdot m = m. \tag{5.1}$$

Lets start with the first one we can define μ as [Morphism](#) in the following way $\mu : M \times M \rightarrow M$ where $M \times M$ is [Product](#) ([Example 2.12](#)) in [Set category](#). I.e. $M, M \times M \in \text{ob}(\mathbf{Set})$ and $\mu \in \text{hom}(\mathbf{Set})$. Consider another objects of [Set](#): $A = M \times (M \times M)$ and $A' = (M \times M) \times M$. They are not the same but there is a trivial [Isomorphism](#) between them $A \cong_\alpha A'$, where

$$\alpha(x, (y, z)) = ((x, y), z).$$

$$\begin{array}{ccc}
M \times (M \times M) & \xrightarrow{\alpha} & (M \times M) \times M \\
\downarrow \eta \times \eta \times \mathbf{1} & & \downarrow \eta \times \eta \times \mathbf{1} \\
M \times M & \xrightarrow{\mu} & M
\end{array}$$

Figure 5.1: Commutative diagram for $\mu \circ (\mu \times \mathbf{1}_{M \rightarrow M}) = \mu \circ (\mathbf{1}_{M \rightarrow M} \times \mu) \circ \alpha$.

Consider the action of [Product of morphisms](#) $\mathbf{1}_{M \rightarrow M} \times \mu$ on A :

$$\mathbf{1}_{M \rightarrow M} \times \mu(x, (y, z)) = (\mathbf{1}_{M \rightarrow M}(x), \mu(y, z)) = (x, y \cdot z) \in M \times M$$

i.e. $\mathbf{1}_{M \rightarrow M} \times \mu : M \times (M \times M) \rightarrow M \times M$. If we act μ on the result we will get:

$$\begin{aligned}
\mu(\mathbf{1}_{M \rightarrow M} \times \mu(x, (y, z))) &= (\mathbf{1}_{M \rightarrow M}(x), \mu(y, z)) = \\
&= \mu(x, y \cdot z) = x \cdot (y \cdot z) \in M,
\end{aligned}$$

i.e. $\mu \circ (\mathbf{1}_{M \rightarrow M} \times \mu) : M \times (M \times M) \rightarrow M$.

For A' we have the following one:

$$\mu \circ (\mu \times \mathbf{1}_{M \rightarrow M})((x, y), z) = \mu(x \cdot y, z) = (x \cdot y) \cdot z.$$

Monoid associativity requires

$$x \cdot (y \cdot z) = (x \cdot y) \cdot z$$

i.e. the corresponding morphisms commute:

$$\mu \circ (\mu \times \mathbf{1}_{M \rightarrow M}) = \mu \circ (\mathbf{1}_{M \rightarrow M} \times \mu) \circ \alpha.$$

This corresponding diagram is shown in fig. 5.1.

Very often the isomorphism α is omitted i.e.

$$M \times (M \times M) = (M \times M) \times M = M^3$$

and the morphism equality is written as follow

$$\mu \circ (\mu \times \mathbf{1}_{M \rightarrow M}) = \mu \circ (\mathbf{1}_{M \rightarrow M} \times \mu)$$

$$\begin{array}{ccc}
M^3 & \xrightarrow{\quad} & M \times M \\
\downarrow \eta \times \mathbf{1} & \searrow \mathbf{1}_{M \rightarrow M} \times \mu & \downarrow \eta \\
M \times M & \xrightarrow{\quad \mu \quad} & M
\end{array}$$

Figure 5.2: Commutative diagram for $\mu \circ (\mu \times \mathbf{1}_{M \rightarrow M}) = \mu \circ (\mathbf{1}_{M \rightarrow M} \times \mu)$.

The corresponding commutative diagram is shown in fig. 5.2.

For (5.1) consider a morphism η from [Singleton](#)¹ $I = \{0\}$ to a special element $e \in M$ such that $\forall m \in M : e \cdot m = m \cdot e = m$. I.e. $\eta : I \rightarrow M$ and $e = \eta(0)$. Consider 2 sets $B = I \times M$ and $B' = M \times I$. We have 2 [Isomorphisms](#): $B \cong_\lambda M$ and $B' \cong_\rho M$ where

$$\lambda(m) = 0 \times m$$

and

$$\rho(m) = m \times 0.$$

If we apply [Product of morphisms](#) $\eta \times \mu$ and $\mu \times \eta$ on B and B' respectively then we get

$$\begin{aligned}
\eta \times \mathbf{1}_{M \rightarrow M} (0 \times m) &= e \times m, \\
\mathbf{1}_{M \rightarrow M} \times \eta (m \times 0) &= m \times e.
\end{aligned}$$

If we apply μ on the result then we get

$$\begin{aligned}
\mu (\eta \times \mathbf{1}_{M \rightarrow M} (0 \times m)) &= \mu (e \times m) = e \cdot m, \\
\mu (\mathbf{1}_{M \rightarrow M} \times \eta (m \times 0)) &= \mu (m \times e) = m \cdot e.
\end{aligned}$$

The (5.1) leads to the following equation for morphisms

$$\mu \circ (\eta \times \mathbf{1}_{M \rightarrow M}) \circ \rho = \mu \circ (\mathbf{1}_{M \rightarrow M} \times \mu) \circ \lambda = \mathbf{1}_{M \rightarrow M}$$

or the commutative diagram show on fig. 5.3.

Before given a formal definition lets look at the operations were used for the construction. The first one is the product of 2 objects:

$$M \times M.$$

¹ It also is called [4] as a one point set

Figure 5.3: Commutative diagram for $\mu \circ (\eta \times \mathbf{1}_{M \rightarrow M}) \circ \lambda = \mu \circ (\mathbf{1}_{M \rightarrow M} \times \mu) \circ \rho = \mathbf{1}_{M \rightarrow M}$.

We also have 2 pairs of morphisms:

$$\begin{aligned} \mu &: M \times M \rightarrow M, \\ \mathbf{1}_{M \rightarrow M} &: M \rightarrow M. \end{aligned}$$

and

$$\begin{aligned} \eta &: I \rightarrow M, \\ \mathbf{1}_{M \rightarrow M} &: M \rightarrow M. \end{aligned}$$

The pairs can be combined into one using [Product of morphisms](#) as follows:

$$\begin{aligned} \mu \times \mathbf{1}_{M \rightarrow M} &: (M \times M) \times M \rightarrow M \times M, \\ \mathbf{1}_{M \rightarrow M} \times \mu &: M \times (M \times M) \rightarrow M \times M \end{aligned}$$

and

$$\begin{aligned} \eta \times \mathbf{1}_{M \rightarrow M} &: I \times M \rightarrow M \times M, \\ \mathbf{1}_{M \rightarrow M} \times \eta &: M \times I \rightarrow M \times M. \end{aligned}$$

The same structure ² is used by [Functor](#) and especially by [Bifunctor](#) ([Example 3.15](#)).

Now we are ready to provide the monoid definition in the terms of morphisms.

Definition 5.1 (Monoid). Consider [Set category](#) \mathbf{C} with a [Singleton](#) $t \in \text{ob}(\mathbf{C})$. The [Cartesian product](#) with [Product of morphisms](#) form a [Bifunctor](#) \times (see [example 3.15](#)). The object $m \in \text{ob}(\mathbf{C})$ is called *monoid* if the following conditions satisfied:

²not only objects mapping but also morphisms mapping

1. there is a **Morphism** $\mu : m \times m \rightarrow m$ in the category
2. there is another morphism $\eta : t \rightarrow m$
3. the morphisms satisfy the following conditions:

$$\mu \circ (\mu \times \mathbf{1}_{M \rightarrow M}) = \mu \circ (\mathbf{1}_{M \rightarrow M} \times \mu) \circ \alpha, \quad (5.2)$$

$$\mu \circ (\eta \times \mathbf{1}_{M \rightarrow M}) \circ \lambda = \mu \circ (\mathbf{1}_{M \rightarrow M} \times \mu) \circ \rho = \mathbf{1}_{M \rightarrow M} \quad (5.3)$$

where α (associator) is an **Isomorphism** between $m \times (m \times m)$ and $(m \times m) \times m$. λ, ρ are another isomorphisms:

$$m \cong_{\lambda} t \times m$$

and

$$m \cong_{\rho} m \times t$$

5.2 Monoidal category

As we saw in the categorical definition for monoid (see definition 5.1) the category \mathbf{C} should satisfy several conditions to have an object as monoid. Lets formalise the conditions.

Definition 5.2 (Monoidal category). A category \mathbf{C} is called *monoidal category* if it is equipped with a **Monoid** structure i.e. there are

- **Bifunctor** $\otimes : \mathbf{C} \times \mathbf{C} \Rightarrow \mathbf{C}$ called *monoidal product*
- an **Object** e called unit object or identity object

The elements should satisfy (up to **Isomorphism**) several conditions: associativity:

$$a \otimes (b \otimes c) \cong_{\alpha} (a \otimes b) \otimes c,$$

where α is called associator. e can be treated as left and right identity:

$$a \cong_{\lambda} e \otimes a,$$

$$a \cong_{\rho} a \otimes e,$$

where λ, ρ are called as left and right unitors respectively.

In the **Set category** we have \times as the monoidal product (see example 3.15). There is a morphism η from terminal object t to e [3] (see definition 5.1).

Definition 5.3 (Strict monoidal category). A [Monoidal category](#) \mathbf{C} is said to be strict if the associator, left unitor and right unitors are all identity morphisms i.e.

$$\alpha = \lambda = \rho = \mathbf{1}_{C \rightarrow C}.$$

Remark 5.4 (Monoidal product). The monoidal product is a binary operation that specifies the exact monoidal structure. Often it is called as *tensor product* but we will avoid the naming because it is not always the same as the [Tensor product](#) introduced for [Hilbert spaces](#). We also note that the monoidal product is a [Bifunctor](#).

5.3 Category of endofunctors

The [Fun category](#) ([Example 4.2](#)) is an example of a category. We can apply additional limitation and consider only [Endofunctors](#) i.e. we will look at the category $[\mathbf{C}, \mathbf{C}]$ - category of functors from category \mathbf{C} to the same category. One of the most popular math definition of a monad is the following: “All told, a monad in X is just a monoid in the category of endofunctors of X ”[4]. Later we will give an explanation for that one.

We start with the formal definition of category of endofunctors and a tensor product in the category

Definition 5.5 (Category of endofunctors). Let \mathbf{C} is a category, then $[\mathbf{C}, \mathbf{C}]$ - category of functors from category \mathbf{C} to the same category is called the category of endofunctors.

The monoidal product in the category is the functor composition.

Definition 5.6 (Monad). The monad M is an [Endofunctor](#) with 2 [Natural transformations](#):

1. $\eta : \mathbf{1}_{\mathbf{C} \Rightarrow \mathbf{C}} \rightarrow M$
2. $\mu : M \circ M \rightarrow M$

where $\mathbf{1}_{\mathbf{C} \Rightarrow \mathbf{C}}$ is [Identity functor](#).

The η, μ should satisfy the following conditions:

$$\begin{aligned} \mu \circ M\mu &= \mu \circ \mu M, \\ \mu \circ M\eta &= \mu \circ \eta M = \mathbf{1}_{M \rightarrow M}, \end{aligned} \tag{5.4}$$

where $M\mu, M\eta$ - [Right whiskerings](#), $\mu M, \eta M$ - [Left whiskerings](#), $\mathbf{1}_{M \rightarrow M}$ - [Identity natural transformation](#) for M . [Vertical composition](#) is used in the equations.

The monad will be denoted later as $\langle M, \mu, \eta \rangle$.

Lets look at the requirements (5.4) more closely. Notice that the functor composition is associative:

$$M \circ (M \circ M) = (M \circ M) \circ M = M^3.$$

Secondly all rewrite it with (4.2) and (4.3) as follows

$$\begin{aligned} \mu \circ (\mathbf{1}_{M \rightarrow M} \star \mu) &= \mu \circ (\mu \star \mathbf{1}_{M \rightarrow M}), \\ \mu \circ (\mathbf{1}_{M \rightarrow M} \star \eta) &= \mu \circ (\eta \star \mathbf{1}_{M \rightarrow M}) = \mathbf{1}_{M \rightarrow M}. \end{aligned} \quad (5.5)$$

Thus we can notice that the pair of operations (composition \circ and [Horizontal composition](#) \star) forms the bifunctor (see [Bifunctor in category of functors](#) ([Remark 4.5](#))).

The morphism $\mathbf{1}_{M \rightarrow M} \star \mu$ acts on $M \circ (M \circ M)$ as

$$\mathbf{1}_{M \rightarrow M} \star \mu : M \circ (M \circ M) \rightarrow M \circ (M \otimes M)$$

thus

$$\mu \circ (\mathbf{1}_{M \rightarrow M} \star \mu) : M \circ (M \circ M) \rightarrow M \otimes (M \otimes M).$$

Similarly

$$\mu \circ (\mu \star \mathbf{1}_{M \rightarrow M}) : (M \circ M) \circ M \rightarrow (M \otimes M) \otimes M.$$

I.e. the both morphisms start at the same object M^3 and finish also at the same point. The equality

$$\mu \circ (\mathbf{1}_{M \rightarrow M} \star \mu) = \mu \circ (\mu \star \mathbf{1}_{M \rightarrow M}) \quad (5.6)$$

is similar to the conditions on the fig. 5.2 and can be rewritten on fig. 5.4. Thus if we compare (5.6) and (5.2) then we can say that they are same if we replace \star sign with \times one. I.e. in the case we can say that the monad looks like a [Monoid](#).

For the identity element consider the same trick: replace in (5.3) tensor product \times with [Horizontal composition](#) \star and identity morphism $\mathbf{1}_{M \rightarrow M}, \rho, \lambda$ with identity natural transformation $\mathbf{1}_{M \rightarrow M}$. The result will be the following:

$$\mu \circ (\eta \times \mathbf{1}_{M \rightarrow M}) \circ \lambda = \mu \circ (\mathbf{1}_{M \rightarrow M} \times \mu) \circ \rho = \mathbf{1}_{M \rightarrow M}$$

will be replaced with

$$\mu \circ (\eta \star \mathbf{1}_{M \rightarrow M}) = \mu \circ (\mathbf{1}_{M \rightarrow M} \star \mu) = \mathbf{1}_{M \rightarrow M}$$

that is the exact we want to get (see second equation of (5.5)).

Figure 5.4: Monad as monoid in the category of endofunctors.

5.4 Kleisli category. Monads in programming languages

Definition 5.7 (Kleisli category). Let \mathbf{C} is a category, M is an [Endofunctor](#) and $\langle M, \mu, \eta \rangle$ is a [Monad](#). Then we can construct a new category \mathbf{C}_M that is called as *Kleisli category* as follows:

$$\begin{aligned} \text{ob}(\mathbf{C}_M) &= \text{ob}(\mathbf{C}), \\ \text{hom}_{\mathbf{C}_M}(a, b) &= \text{hom}_{\mathbf{C}}(a, M(b)) \end{aligned}$$

i.e. objects of categories \mathbf{C} and \mathbf{C}_M are the same but morphisms from \mathbf{C}_M form a subset of morphisms \mathbf{C} : $\text{hom}(\mathbf{C}_M) \subset \text{hom}(\mathbf{C})$.

5.4.1 Programming languages

[Kleisli category](#) widely spread in programming especially it provides good description for different types of computations, for instance [7, 6]

- **Partiality** i.e. then a function not defined for each input, for instance the following expression is undefined (or partially defined) for $x = 0$:

$$f(x) = \frac{1}{x}$$
- **Non-Determinism** i.e. then multiply output are possible
- **Side-effects** i.e. TBD
- **Exception** i.e. TBD
- **Continuation** i.e. TBD

- **Interactive input** i.e. TBD
- **Interactive output** i.e. TBD

TBD

5.5 Examples

5.5.1 Programming languages

Haskell

Example 5.8 (Monad). [Hask] In Haskell monad can be defined from `Functor` (Example 3.3) as follows ³

```
class Functor m => Monad m where
  return :: a -> m a
  (>>=)  :: m a -> (a -> m b) -> m b
```

To show how this one can be get we can start from a definition that is similar to the math definition:

```
class Functor m => Monad m where
  return :: a -> m a
  join   :: m (m a) -> m a
```

where `return` can be treated as η and `join` as μ . In the case the bind operator `>>=` can be implemented as follows

```
(>>=) :: m a -> (a -> m b) -> m b
ma >>= f = join ( f ma )
```

Example 5.9 (Maybe monad). [Hask] Consider the monad definition that is most close to math definition first:

```
class Functor m => Monad m where
  return :: a -> m a
  join   :: m (m a) -> m a
```

the Maybe monad can be implemented as follows

```
instance Monad Maybe where
  return = Just
  join Just( Just x) = Just x
  join _ = Nothing
```

TBD

³real definition is quite different from the presented one

C++

TBD

Scala

Example 5.10 (Monad). [Scala] The monad concept in Scala is more close to formal math definition for [Monad](#). It can be defined as follows ⁴

```
trait M[A] {
  def flatMap[B](f: A => M[B]): M[B]
}

def unit[A](x: A): M[A]
```

I.e. `flatMap` can be considered as μ and `unit` as η .

TBD

5.5.2 Quantum mechanics

Definition 5.11 (Tensor product). TBD

The tensor product in quantum mechanics is used for representing a system that consists of multiple systems. For instance if we have an interaction between an 2 level atom (a is excited state b as a ground state) and one mode light then the atom has its own Hilbert space \mathcal{H}_{at} with $|a\rangle$ and $|b\rangle$ as basis vectors. Light also has its own Hilbert space \mathcal{H}_f with Fock state $\{|n\rangle\}$ as the basis. ⁵ The result system that describes both atom and light is represented as the tensor product $\mathcal{H}_{at} \otimes \mathcal{H}_f$.

The morphisms of **FdHilb** category have a connection with [Tensor product](#). Consider the so called Hilbert-Schmidt correspondence for finite dimensional Hilbert spaces i.e. for given \mathcal{A} and \mathcal{B} there is a natural isomorphism between the tensor product and linear maps (aka morphisms) between \mathcal{A} and \mathcal{B} :

$$\mathcal{A}^* \otimes \mathcal{B} \cong \text{hom}(\mathcal{A}, \mathcal{B})$$

where \mathcal{A}^* - [Dual space](#).

TBD

⁴real definition is quite different from the presented one

⁵ Really the \mathcal{H}_f is infinite dimensional Hilbert space and seems to be out of our assumption about **FdHilb** category as a collection of finite dimensional Hilbert spaces only.
